Expressions/Grammar/Design Choices Relative to Lox:

My project follows most of the characteristics and rules of lox. I've made minor changes like print being changed to say but for the most part it replicates lox. I plan on adding more minor changes in the future to make the language more unique.

File/Test Instructions:

The lab3 test file just needs to be executed within the same file directory as main.py. This file will run a bunch of unit tests using the unittest imported module. This wasn't implemented for other test files so this one should offer more in depth test results.

Test File Results:

Of all the tests added to the lab3 test file, there were not any errors in the output. All tests met their expected results, including tests which look for error responses. Each test is scanned into tokens and ran through the AST printer, which gives a result in the terminal. The first set of tests involve literal testing, which includes verifying that numbers, strings, and statementings like True, False, etc are properly scanned and displayed through the AST. Next is all binary operators and tests involving mathematical equations. After this there are a few error tests to ensure that parentheses and other symbol placement follows syntax.
